Problem

How do I get a core file when a Container crashes?

Solution

The problem is that the default limit for the size of core files is smaller than a typical Container core.

Do the following before starting your container:

• ulimit -c 100000000

To test:

- · start a container
- check the PID
- > kill -SIGSEGV

You should get the following message in the window where the container runs:

• Segmentation fault (core dumped)

You can find more details here:

• http://aplawrence.com/Linux/limit_core_files.html
